

A Formal Approach to Decipher a Mixture of Genetic and Metabolic Networks

Fabien Corblin, Eric Fanchon, Laurent Trilling

Workshop *Toward Systems Biology*

31 mai 2011

General problems

- exploration of regulatory biological networks
 - qualitative and incomplete data
 - complex relation between structure and global behavior
- modeling of regulatory biological networks
 - which players ?
 - which interactions ? kinetics ? thresholds ?
 - which behaviors ?
 - which possible correction to a deficiency of the model/system ?

Motivation

Example of discrete modeling (Thomas networks)

generic structure

possible behavior 1

possible behavior 2

Variables: **kinetics**, **thresholds**, existence, composition of **interactions**, **behaviors**

Specific problems

Avoid trial-error process – Consider in intension a class of models

Solution

Use of formal approach – Constraint approach

Structure

- nodes of the network (molecular species)
- reactions/**interactions** (conditions about the current position of the system state + effects on the **tendency** of the system)
- **thresholds** of reactions (values are formal entities)

Behaviors

- existence of a **path** (sequence of **transitions**)
- possibility to consider several mutant types
- possibility to consider several input contexts

Relation between structure and behaviors

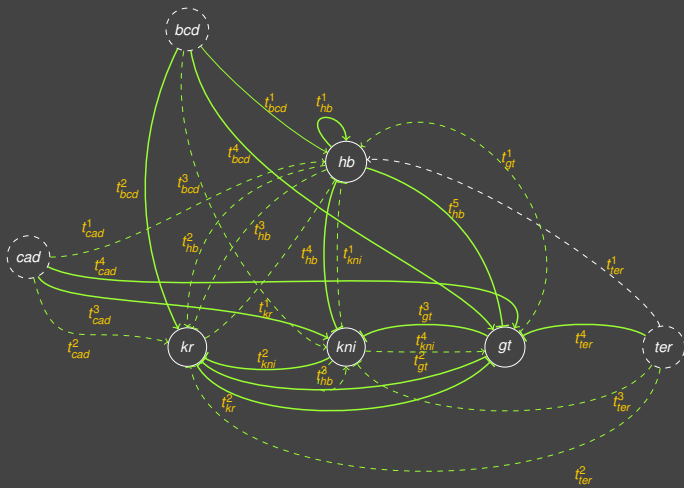

- formalization of Thomas networks (existence of a **path** constrained to follow the **tendencies** of the system in each encounter state),
- interaction signs (increasing tendencies + or decreasing – if the threshold of interaction is crossed)

Example on the network controlling the drosophila embryo segmentation

Knowledge declaration – Example on the network controlling the drosophila embryo segmentation

Structure and interaction signs

Knowledge declaration – Example on the network controlling the drosophila embryo segmentation

Behaviors

type	<i>gt</i>	<i>hb</i>	<i>kr</i>	<i>kni</i>	<i>gt</i>	<i>hb</i>	<i>ter</i>	additional constraints
<i>wt</i>	⌊	⌊	⌊	⌊	⌊	⌊	⌊	
<i>hb0</i>	⌊		⌊	⌊	⌊		⌊	
<i>kr0</i>		⌊				///	///	$S_{gt}^{1,kr0} > 0$
<i>kni0</i>	⌊	⌊	⌊		⌊	///	///	
<i>gt0</i>		⌊	⌊	⌊		///	///	
<i>ter0</i>	⌊	⌊	⌊	⌊	⌊			
<i>bcd0</i>				⌊	⌊	///	///	
<i>cad0</i>	⌊	⌊	⌊			///	///	

Search for the minimal network – Example on the network controlling the drosophila embryo segmentation

Minimal structure

- consistence
- optimization (minimal number of interactions, of thresholds, etc)
- search for properties (positions of steady states, manner to compose the interactions, etc)
- inconsistency correction (relaxation of constraints)

"Genetic" **cellular context** of node N

- region of concentration space defined by the same positioning compared to the thresholds of interactions onto N
- two states in the same **cellular context** have the same "genetic" effects

Tendency of N in these **cellular contexts**

- value toward the direction of evolution of the concentration of N
- modeled by a parameter (not known by default)

Transitions

- from a state $S1$ to a state $S2$ different: only possible if
 - $S1$ and $S2$ are different by only one component N , and
 - $S2_N$ on the same side compared to $S1_N$ that the tendency of N in $S1$ (the trajectory does not contradict the tendency).
- from a state $S1$ to the same state $S1$: only possible if
 - for all N , the tendency of N in $S1$ is equal to $S1_N$.

Semantic of genetic discrete networks – Example

Example of discrete modeling (Thomas networks)

generic structure

possible behavior 1

possible behavior 2

Variables: kinetics, thresholds, existence, composition of interactions, behaviors

Semantic of metabolic networks

Metabolic reaction

- a set of consumed species
- a set of produced species
- an activation condition (enzymes can interact)

"Production" and "consumption" **cellular contexts** of the node N

- region of concentration space defined by the same positioning compared to the thresholds of activation conditions for the production (resp. consumption) of N
- two states in the same "production" (resp. "consumption") **cellular context** have the same "production" (resp. "consumption") effects

Tendency of N in these **cellular contexts**

- value $V \in \{min, current\ value, max\}$ toward the direction of evolution of the concentration of N
- $V = min$ if active consumption and no active production
- $V = max$ if active production and no active consumption
- $V = current\ value$ if no active consumption neither active production
- modeled by a parameter if there exist a conflict (both active production and active consumption)

Transition : idem "genetic" + impossible to contradict the tendency of the arrival state

Semantic of discrete metabolic networks – Example on a complexation-decomplexation reaction $a + b \rightleftharpoons c$

Metabolic reactions

- $\{a, b\} \xrightarrow{S_a \geq t_a^1 \wedge S_b \geq t_b^1} \{c\}$
- $\{c\} \xrightarrow{S_c \geq t_c^1} \{a, b\}$

"Production" and "consumption" **cellular contexts** of node N

- production of $a \Leftrightarrow S_c \geq t_c^1$ (2 "production" cellular contexts for a),
- consumption of $a \Leftrightarrow S_a \geq t_a^1 \wedge S_b \geq t_b^1$,
- production of $c \Leftrightarrow S_a \geq t_a^1 \wedge S_b \geq t_b^1$,
- consumption of $c \Leftrightarrow S_c \geq t_c^1$

Tendency of N in one of these cellular contexts

- for a (idem for b) :
 - = *min*: if $S_a \geq t_a^1 \wedge S_b \geq t_b^1 \wedge S_c < t_c^1$
 - = *max*: if $S_c \geq t_c^1 \wedge (S_a < t_a^1 \vee S_b < t_b^1)$
 - = *current value* = $S_N = S_a$: if $(S_a < t_a^1 \vee S_b < t_b^1) \wedge S_c < t_c^1$
 - = *parameter* $\in \{min, current\ value, max\}$: if $S_a \geq t_a^1 \wedge S_b \geq t_b^1 \wedge S_c \geq t_c^1$

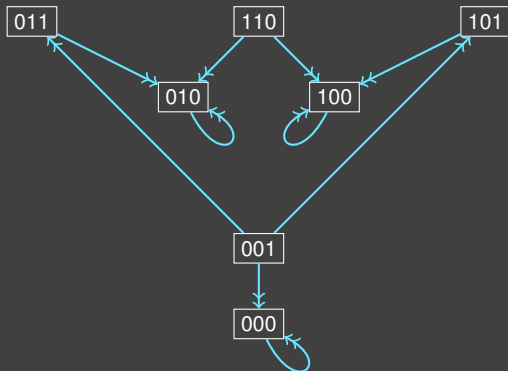

Transition : idem "genetic" + impossible to contradict the tendency of the arrival state

Semantic of discrete metabolic networks – Example on a complexation-decomplexation reaction

Semantic of discrete metabolic networks – Example on a complexation-decomplexation reaction

Semantic of discrete metabolic networks – Example on a complexation-decomplexation reaction

Semantic of discrete metabolic networks – Example on a complexation-decomplexation reaction $a + b \rightleftharpoons c$

abc

cellular contexts of node N

triple of cellular contexts "genetic", "production", and "consumption" (noted

$Cellc_N^{i_{genetic}, i_{production}, i_{consumption}}$ or just $Cellc_N^i$).

Tendency of N in one of these cellular contexts

- if no production and consumption of N : idem genetic semantic,
- if no genetic interaction onto N : idem metabolic semantic,
- else : idem genetic semantics +
Constraints enforcing a (non strict) increasing of the tendency from a (non empty) cellular context $Cellc_N^1$ to a (non empty) cellular context $Cellc_N^2$ if:
 - $Cellc_N^2 = Cellc_N^1 + \text{one production,}$
 - $Cellc_N^2 = Cellc_N^1 - \text{one consumption,}$
 - $Cellc_N^2 = Cellc_N^1 + \text{one additive interaction}$ (true also for genetic part).

- **GNBox environment**
 - formalization: **discrete genetic networks** and biological properties
 - implementation: cooperation of 2 solvers, CP on integers and SAT
 - fonctionnalités: consistency, correction, property inference, optimization
 - formal entities: existence, kinetic and thresholds of interactions, behaviors,
 - publication : F. Corblin, E. Fanchon, L. Trilling. BMC Bioinformatics 2010.
- **SysBiOX environment**
 - formalization : **discrete mixed networks (genetic and metabolic)**
 - implementation: with ASP (Answer Set Programming)
- **Very general**: many functionalities and easy representation of data
- **Completely declarative modeling**: formalizations with constraints (over formal entities)

- application to the toxicity control in human hepatic cells (A. Corlu, F. Morel, INSERM Rennes – J. Nicolas, IRISA-INRIA Rennes).
- application to mammal iron homeostasis (J.-M. Moulis, IMBG-CEA Grenoble).
- study of mixed network properties (as presented here).
- experiment design: language to describe
 - biological properties (objective)
 - controllable perturbations
 - observables.
- technological study for optimization, property inference, and relaxation of constraints (ASP, SMT).
